Quantum computing: algorithms

Prepare initial state

Prepare initial quantum state

Quantum algorithm

Use interference to make wanted outcomes more likely

Measurement outcomes

Measure multiple times

Quantum computing: algorithms

- Quantum algorithms leverage superposition and entanglement to enable new algorithms and manipulate qubits via **quantum operations** (or **gates**).
- Quantum algorithms explore a superposition of solution paths simultaneously.
- Quantum algorithms use **interference** to enhance the **likelihood** of measuring correct solutions.

Quantum operations

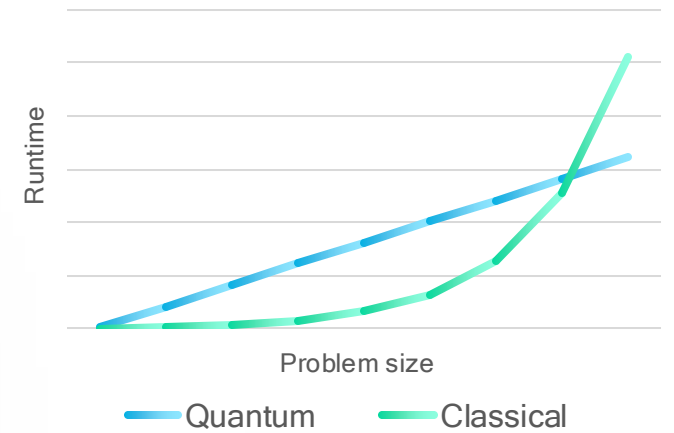

Measurement outcomes

Quantum algorithms vs. Classical algorithms

Quantum algorithms can provide up to **exponential speedup** for certain tasks in domains like simulation, optimization, or machine learning.

Quantum computers do not speed up existing algorithms but allow new types of algorithms

Near-term quantum computing applications compass three main areas

Quantum simulation

Material science, pharmacy, biology,
chemistry, high energy physics

Optimization

Logistics, processes, portfolios, risks

Artificial intelligence
/ machine learning

Model training, pattern recognition

Simple Quantum Algorithms: Bernstein Vazirani

Problem

- Given: A secret (but unknown) code
- Given: A black box, that changes the answer for every 1 in the secret code ($0 \rightarrow 1, 1 \rightarrow 0$)
- **Goal:** identify secret code

Example

secret code = 110

QUIZ TIME!

Develop a strategy for the given problem. How many attempts do you need? Describe your approach.

		1	2	3	4	5	6
0	Nr. 1	Black box					
0	Nr. 2						
0	Nr. 3						
0	Nr. 4						
1	Nr. 5						

— Easy solution

- Set all inputs except one to 0

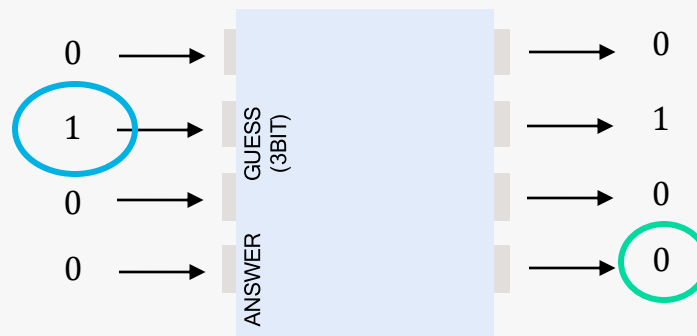

— Easy solution

- Set all inputs except one to 0
- The last qubit indicates if there is a 0 or 1 on this position

Easy solution

- Set all inputs except one to 0
- The last qubit indicates if there is a 0 or 1 on this position
- Repeat for every digit in the secret code

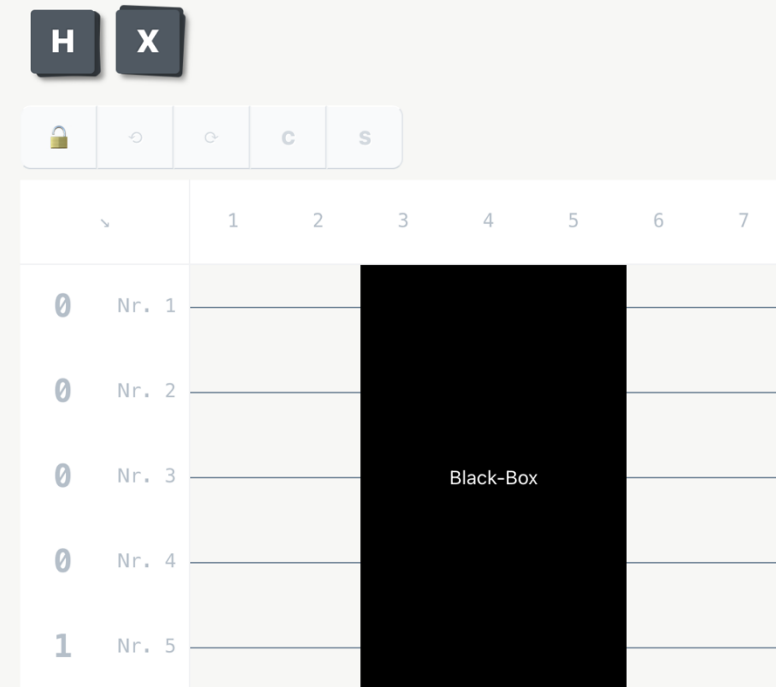

Secret code is: 101 !

QUIZ TIME!

To find out the secret 4-digit code of this black box, prepare an equal superposition of all 5 qubits. Apply a set of **H** also after the black box.

Afterward, open the black box and check how you can retrieve the secret code from the measurement outcomes.

Quantum solution

- Initialize GUESS Qubits with 0, answer qubit with 1

Quantum solution

- Initialize GUESS Qubits with 0, answer qubit with 1
- Apply H gates before and after the black box

Quantum solution

- Initialize GUESS Qubits with 0, answer qubit with 1
- Apply H gates before and after the black box
- Output of GUESS qubits is the secret code 🤖

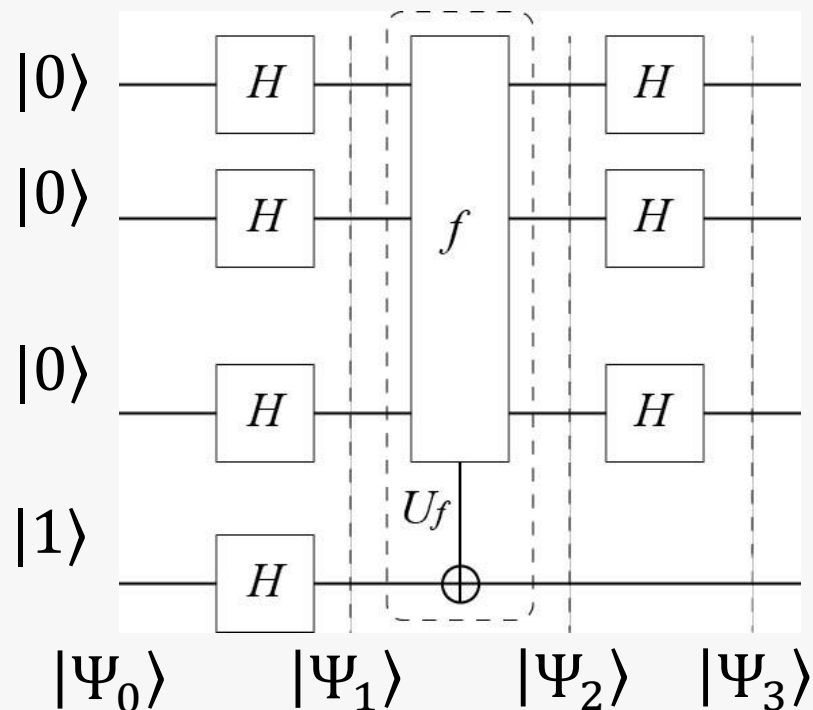

Bernstein-Vazirani algorithm expressed mathematically

- Let $f = c \cdot x = c_{n-1}x_{n-1} \oplus \dots \oplus c_0x_0: S_n \equiv \{0,1, \dots, 2^n - 1\} \rightarrow \{0,1\}. c = c_{n-1} \dots c_1c_0$.
- We need to evaluate f **n times** for n different x to find c classically.
 $x = (100 \dots 0)$ is used to find c_{n-1} , for example.
- The Bernstein-Vazirani algorithm finds c with a **single** query of f .

- $|\Psi_0\rangle = |1\rangle|00 \dots 0\rangle$.
 - $|\Psi_1\rangle = \frac{1}{\sqrt{2}}(|0\rangle - |1\rangle) \frac{1}{\sqrt{2^n}}(|0\rangle + |1\rangle)^{\otimes n}$
 $= \frac{1}{\sqrt{2}}(|0\rangle - |1\rangle) \frac{1}{\sqrt{2^n}} \sum_{x=0}^{2^n-1} |x\rangle$
 - $|\Psi_2\rangle = U_f |\Psi_1\rangle$
 $= \frac{1}{\sqrt{2}} \frac{1}{\sqrt{2^n}} \sum_{x=0}^{2^n-1} |x\rangle (|c \cdot x\rangle - |\neg c \cdot x\rangle) |x\rangle$
 $= \frac{1}{\sqrt{2}}(|0\rangle - |1\rangle) \frac{1}{\sqrt{2^n}} \sum_{x=0}^{2^n-1} (-1)^{c \cdot x} |x\rangle$
- $U_f |y, x\rangle = |y \oplus (c \cdot x), x\rangle$

Bernstein-Vazirani algorithm

- $|\Psi_3\rangle = (I \otimes H^{\otimes n})|\Psi_2\rangle$
 $= \frac{1}{\sqrt{2}} (|0\rangle - |1\rangle) \frac{1}{\sqrt{2^n}} \sum_{x=0}^{2^n-1} (-1)^{c \cdot x} H^{\otimes n} |x\rangle.$
- Recall that
 $H|x_k\rangle = \frac{1}{\sqrt{2}} (|0\rangle + (-1)^{x_k} |1\rangle)$
 $= \frac{1}{\sqrt{2}} \sum_{y_k \in \{0,1\}} (-1)^{x_k y_k} |y_k\rangle.$ Then
 $H^{\otimes n} |x\rangle = (H|x_{n-1}\rangle)(H|x_{n-2}\rangle) \dots (H|x_0\rangle)$
 $= \frac{1}{\sqrt{2^n}} \sum_{y_k \in \{0,1\}} (-1)^{x_{n-1}y_{n-1} + \dots + x_0 y_0} |y_{n-1} \dots y_0\rangle$
 $= \frac{1}{\sqrt{2^n}} \sum_{y=0}^{2^n-1} (-1)^{x \cdot y} |y\rangle.$

- $|\Psi_3\rangle = \frac{1}{\sqrt{2}} (|0\rangle - |1\rangle) \frac{1}{2^n} \sum_{x_k, y_k \in \{0,1\}} (-1)^{c \cdot x + x \cdot y} |y\rangle.$
- Let $y = c$. Then the phase is 1 independently of x and $\sum_{x_k \in \{0,1\}} 1 = 2^n$.
- If $y \neq c$, a half of x gives $(-1)^{c \cdot x + x \cdot y} = +1$ and the rest $(-1)^{c \cdot x + x \cdot y} = -1$.

Bernstein-Vazirani algorithm

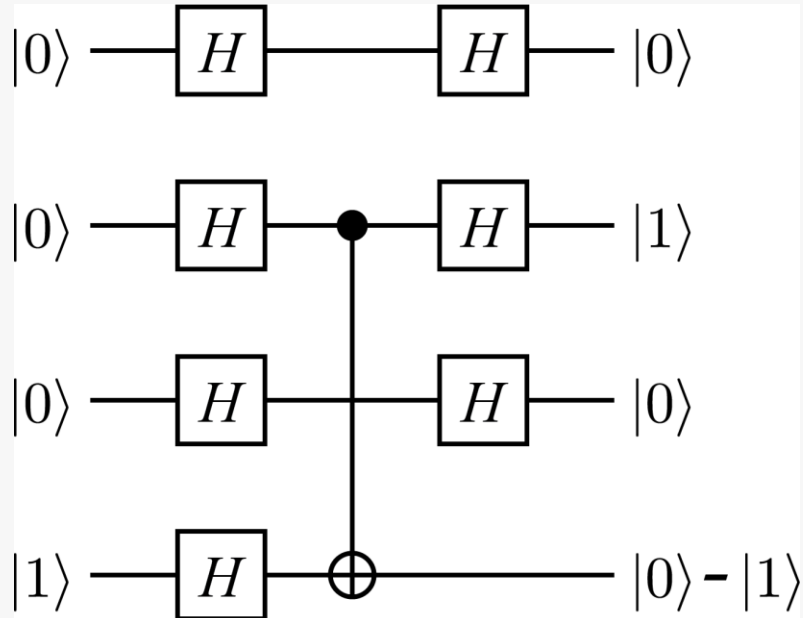

- $|\Psi_3\rangle = \frac{1}{\sqrt{2}} (|0\rangle - |1\rangle)|c\rangle$.
- A **single** measurement of the n qubits reveals $c = c_{n-1}c_{n-2} \dots c_1c_0$.

Bernstein-Vazirani algorithm

Another example:

- Let us consider U_f for $c = 010$ for example.

Exercise: Show that

Exercise

- Find the oracle U_f for $c = 110$.

— Conclusion: Quantum algorithms

- Quantum algorithms use **hybrid manner**, utilizing both quantum and classical computing resources
- Quantum algorithms are **adaptable to a range of problems**. Developing a deeper understanding of suitable problems and how they are mapped is essential
- Achieving **early quantum advantage** requires the strategic alignment of purpose-built algorithms with targeted problems and the compatible hardware
